Abstract: In this letter, a high-performance inverter based on amorphous indium-gallium-zinc oxide thin-film transistors (TFTs) is fabricated, which consists of an enhancement mode driver and a depletion mode load. By applying an area-selective laser annealing technique, the threshold voltage (V th) of the load TFT could be tuned from positive to negative gate voltage.

The experimentally extracted voltage gain, which is defined to be v GAIN = ?V OUT /?V IN, where V OUT and V IN are the output and input voltage of the inverter, respectively, is equal to 5-10 and a clear and abrupt transition for the inverter output voltage from the logical high- to low-state was observed.

A very interesting solution consists of special so-called "hybrid" inverters that accept as input both a string of photovoltaic panels and the 230 V AC power grid; a contactor driven by the control electronics, allows switching the load to the grid or to the output of the inverter according to the power demand, i.e., the presence of ...
