#### Photovoltaic inverter derating operation

What is derating a solar inverter?

Derating is the controlled reduction of the inverter power. In normal operation, inverters operate at their maximum power point. At this operating point, the ratio between PV voltage and PV current results in the maximum power. The maximum power point changes constantly depending on solar irradiation levels and PV module temperature.

Does temperature derating affect a PV inverter?

In this case, the maximum DC voltage of the inverter acts more as a technical boundary than a normal operating curve. There is no PV array operating point that requires the inverter to feed in at full power at temperatures above 31°C (at 800 V). On principle, temperature derating has no negative effects on the inverter.

What is a temperature derating inverter?

Temperature derating prevents the sensitive semiconductors in the inverter from overheating. Once the permissible temperature on the monitored components is reached, the inverter shifts its operating point to a reduced power level. The power is reduced in steps. In extreme cases, the inverter will shut down completely.

What is a derating behavior of an inverter?

This behavior reduces the inverter output power(derating). In this document, the derating behavior of the inverters is shown in graphic form. The derating behavior is given for the minimum MPP voltage, the rated input voltage and the maximum MPP voltage.

What causes a PV system to derate?

Derating rarely occurs when the PV system is well matched. Derating is more common when the inverter is undersized relative to the PV array(see Section 2,page 2 for the causes of frequent temperature derating). You can determine the ideal design for your PV system with the "Sunny Design" software.

How to avoid derating at peak PV array outputs?

In order to avoid derating at peak PV array outputs, an inverter with a nominal power of more than 100% of the PV array power could be selected. However, this would shift a larger proportion of partial load yields to a range within which the inverter is relatively inefficient.

The proposed alternate method for the temperature derating test is validated by carrying out the test on a three-phase 60 kW grid tie solar PV inverter with input DC MPPT voltage of 850 V.

As shown in Figure above, a complete PV grid-connected system includes PV modules, PV inverters, public grids, and other components. In photovoltaic module systems, photovoltaic inverters are the key component. Note: If the selected PV module requires the positive or negative grounding, please

derating"" in inverters. The inverter is a major component of photovoltaic (PV) systems either autonomous or grid con-nected. It affects the overall performance of the PV system. Any problems or issues with an inverter are difficult to notice unless the inverter shuts down. Derating protects sensitive components and prolongs their lifetime.
