What is shafting system in a wind turbine?

Typical Structure and mechanical model of shafting system in wind turbines The shafting system of the wind turbine has many structural types. A typical structure with two bearings (DTRB and CRB) and a main shaft is shown in Figure 1. The flange at the left side of the shaft is used to connect the hub and the shaft.

What is a wind turbine main shaft arrangement?

A wind turbine's main shaft arrangement is part of a geared,hybrid,or direct drive design. Whatever the arrangement,it must withstand axial and radial loads and operate under harsh,continuously changing conditions. Wind turbine main shaft bearings spin at relatively low speeds of around 10 rpm. Also,they experience continually variable loads.

What is the model of the wind turbine main shaft?

The model of the wind turbine main shaft. The FEM analysis of the main shaft was conducted with the applied loads on the main shaft under the rated load condition and impact condition, respectively. In order to obtain a reasonable stress distribution of the main shaft, the key point is to obtain the realistic loads of the main shaft.

Why is shaft strength important in wind turbines?

The improvement of shaft strength decreases the possibility of crack formation and its growth, thus enhancing the reliability of the main shaft. This analysis process and the results of this study can provide a reference in shaft fracture analysis and also technical support for improvement in the design of wind turbine main shafts.

What is the nominal shaft rotation speed of a wind turbine?

According to the documentation of the considered wind turbine, the nominal shaft rotation speed is n nom = 320 rpm. When considering the concept of a hybrid bearing for the wind turbine shaft, it was assumed that the plain bearing takes over the total vertical load to the shaft at a boundary rotation speed of

How fast do wind turbine bearings spin?

Wind turbine main shaft bearings spin at relatively low speeds of around 10 rpm. Also, they experience continually variable loads. In offshore applications, turbine bearings may be exposed to corrosive seawater. Bearings in the largest turbines have an internal bore of more than 2m.

Turbine power increases with the cube of wind velocity. For example, a turbine at a site with an average wind speed of 16 mph would produce 50 percent more electricity than the same turbine at a site with average wind
